

*Aenigma* are strikingly similar. Species of both share a creeping rhizome, echinate to papillose and trivalvate ovaries, an entire to triblobed lip, and a footless column with a dilated apex and apical anther. Also, the lip in some species of subgenus *Aenigma* surrounds the column or nearly so, as in *Andinia* (Luer, 1994, 2000). The genus is primarily Andean, ranging from Colombia to Bolivia.

## ANDINIA

Partially on the basis of our unpublished results from DNA sequencing, Luer (2000) segregated subgenus *Andinia* Luer from *Salpistele* Dressler and raised it to generic rank, encompassing two species—*Andinia dielsii* (Mansf.) Luer and *A. pensilis* (Schltr.) Luer.

Since the submission of the broad phylogenetic study (Pridgeon, Solano, and Chase, 2001), we sequenced material of *Pleurothallis lappacea* of subgenus *Aenigma* Luer and reanalyzed the large ITS matrix of that study using the same protocol but including *P. lappacea*. It was sister to *Andinia pensilis* with 99% bootstrap support (Fig. 2). Accordingly, we have expanded the concept of *Andinia* here to include *P.* subgenus *Aenigma*.
