

## THE *PROSTHECHEA PRISMATOCARPA* COMPLEX (ORCHIDACEAE: LAELIINAE) IN COSTA RICA, WITH A NEW SPECIES, *P. TARDIFLORA*

FRANCO PUPULIN

Jardín Botánico Lankester, Universidad de Costa Rica

Research Associate, Marie Selby Botanical Gardens

P.O. Box 1031-7050 Cartago, Costa Rica, A.C. - fpupulin@cariari.ucr.ac.cr

**ABSTRACT.** The complex of *Prosthechea prismatocarpa* (Orchidaceae: Laeliinae) in Costa Rica is revised. A key to the species of the group is presented, together with their current taxonomy. A new species is described, *P. tardiflora* Mora-Retana ex Pupulin. The new species may be distinguished within the complex by the abbreviate rhizome, the inflorescence produced on the pseudobulb of the previous year, the non-fragrant flowers, the acute and basally reflexed sepals, the wide isthmus, and the short midlobe of the lip.

**RESUMEN.** Se presenta una revisión del complejo de *Prosthechea prismatocarpa* (Orchidaceae: Laeliinae) en Costa Rica, con una clave de las especies y su taxonomía actualizada. Se describe una nueva especie, *P. tardiflora* Mora-Retana ex Pupulin. Dentro del complejo, la nueva especie se puede reconocer por el rizoma corto, la inflorescencia producida en el pseudobulbo del año anterior, las flores inodoras, los sépalos agudos y doblados en la base, el istmo del labelo ancho y el lóbulo medio corto.

**KEY WORDS:** Orchidaceae, *Prosthechea prismatocarpa* complex, *Prosthechea tardiflora*, Costa Rica

With their erect, many-flowered inflorescences, *Prosthechea prismatocarpa* (Rchb.f.) W.E. Higgins and the allied species are among the showiest orchids of Costa Rican flora. Since the time of its original description, the concept of *Epidendrum prismatocarpum* was used in a broad sense (Reichenbach 1883, 1886, Schlechter 1923, Teuscher 1969, Mora-Retana & Atwood 1992) to include populations which may be distinguished on the basis of ecological data (Fig. 1, 2) and morphological characters (Fig. 3). The need of a careful study of the group was pointed out by Dressler (1993: 58) and new insights were proposed by Mora-Retana and García-Castro (1990), and Pupulin (2001a, 2001b).

The complex of *P. prismatocarpa* as a whole may be recognized by the pyriform, 2- to rarely 3-leaved pseudobulbs, the showy flowers produced on long, erect inflorescences, the usually 3-lobed lip (entire in *P. brassavolae* (Rchb. f.) W.E. Higgins) with the median lobe larger than lateral lobes, acute to attenuate, and the column with large lateral teeth

with a deep sinus and a median fimbriate tooth. As presently known, the group is eminently Central American in distribution. With the exception of *P. brassavolae*, ranging north to the States of Oaxaca and Veracruz in Mexico (Espejo Serna & López-Ferrari 1997), the remaining species of the group are restricted to southern Mesoamerica, with a center of diversity in Costa Rica.

### KEY TO THE COSTA RICAN SPECIES OF THE *PROSTHECHEA PRISMATOCARPA* COMPLEX

1. Lip entire, without basal lobes ..... *P. brassavolae*
1. Lip 3-lobed, provided with 2 small lobes at the base ..... 2
2. Midlobe of lip cordate-sagittate, caudate; lip > 4 cm long; sepals and petals unspotted ..... *P. ionocentra*
2. Midlobe of lip triangular, attenuate; lip < 3.5 cm long; sepals and petals spotted brown ..... 3
3. Inflorescence produced from the pseudobulb of the previous year; rhizome short ..... *P. tardiflora*
3. Inflorescence produced from the new pseudobulb; rhizome elongate ..... 4

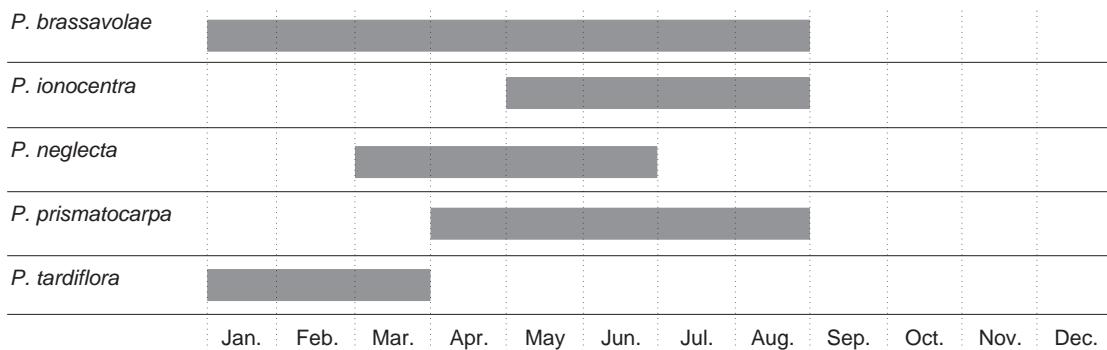

FIGURE 1. Phenology of the Costa Rican species of *Prosthechea prismatocarpa* complex.

4. Sepals adaxially papillose; ovary swollen; inflorescence lax..... *P. neglecta*
4. Sepals adaxially glabre; ovary clavate; inflorescence dense..... *P. prismatocarpa*

#### TAXONOMY

TYPE: PANAMA. Chiriquí Vulkan auf Steinen, 1000 ft., Warszewicz s.n. (W!).

Epiphytic in premontane to montane wet forest, at 1100–2700 m elevation. Mexico to western Panama. In Costa Rica it occurs on both drainages of Cordillera de Guanacaste, Tilarán and Talamanca. Flowering January to August.

SPECIMENS SEEN: COSTA RICA. Alajuela: Alto de La Palma de San Ramón, 1225 m, 6.XI.1923, A. M. Brenes 660 (CR!); La Palma de San Ramón, 1150 m, 26.VII.1924, A. M. FIG. 4.

TYPE: COSTA RICA. Guanacaste: Santa Cruz, from Juan Día toward Vista al Mar, 500–600 m, collected by Raúl Cascante Arias, 1992, flowered in cultivation at Tambor de Alajuela, 15 January 2001, F. Pupulin 2806 (holotype, USJ!).

Herba epiphytica Prosthecheae prismatocarpeae (Rchb.f.) W.E. Higgins similis, rhizoma perbrevi, pseudobulbis complanatis ovatis vel suborbicularis, inflorescencia a caule anni praecedenti producta, labello obovato-subpandurato, isthmo lato, lobo mediano breviter triangulari, callo lamina plana vescicula antice binata superposita recedit.

Plant epiphytic, with a very short rhizome covered by papyraceous, brown bracts. Roots flexuous,

glabrous. *Pseudobulbs* ovate to broadly ovate to suborbicular, laterally complanate, 6.2–8.0 cm long, 3.4–5.0 cm wide, 2- to rarely 3-foliate at apex. *Leaves* separate by an internode to 1.4 cm long, narrowly elliptic to liner-elliptic, fleshy, obtuse to retuse, narrowed to a conduplicate, subsessile base, 15–18 cm long, 3–4 cm wide. *Inflorescence* terminal, an erect, dense raceme produced from the apex of the previous pseudobulb, to 27 cm long including the peduncle, many-flowered, emerging from a papery bract to 8 cm long. *Ovary* subclavate, slightly winged, about 2.5 cm long including the pedicel. *Flowers* rather large, with sepals and petals free, spreading, yellowish cream to ochre, the sepals and petals spotted with purple, the lip cream white with three rose-purple blotches. *Dorsal sepal* narrowly-lanceolate, acute, somewhat reflexed at the base, adaxially verruculose, to 23 mm long, 5 mm wide. *Lateral sepals* obliquely lanceolate, subfalcate, minutely apiculate, dorsally subcarinate and slightly concave toward the apex, convex at the base, 22 mm long, 6.5 mm wide. *Petals* linear-elliptic, acute, 22 mm long, 3.5 mm wide. *Lip* 3-lobed, obovate-subpandurate, the basal claw adnate to the column, 20 mm long, 9.5 mm wide; the lateral lobes rounded to subfalcate; the midlobe ovate-triangular, acute, concave toward the apex; disc with a callus formed by a flat lamina with a fleshy vesicle bifurcate at apex. *Column* stout, semiterete, 13 mm long, provided at the apex with a pair of fleshy, subfalcate, acute lateral teeth, and a central, lacerate-dentate projection. *Anther cap* incumbent, operculate, subquadrate to subspherical, 4-celled. *Pollinia* 4, waxy, narrowly obovate, complanate, on two short, linear, shortly bifid caudicles.

PARATYPES: COSTA RICA. Alajuela: Palmares, orillas del Río Rastrojos, en floración el 26/II/1994, W. Barahona s.n. (USJ!); Palmares, a orillas del Río Jesús María, Marzo de 1994, D.E. Mora s.n. (USJ!). Puntarenas: Aguirre, Villa Nueva, Finca Walker, about 200 m, collected by Mrs. Merli, flowered in cultivation at Gaia Botanical Garden, 20 Apr. 1999, F. Pupulin 1431 (USJ, Spirit!).

DISTRIBUTION: only known from Costa Rica.

ECOLOGY AND PHENOLOGY: epiphytic in rain and seasonally moist forests along the Pacific drainage,

usually restricted to lowlands and premontane warm areas at 200-800 m elevation. Flowering occurs from January to April.

**ETYMOLOGY:** from the Latin *tardiflorus*, “late-flowering,” in allusion to the flowering habit of the species, with the inflorescence emerging from the pseudobulb of the previous year.

The occurrence in Costa Rica of an undescribed species closely related to *P. prismatocarpa* was first noted by the late Dora Emilia Mora-Retana, who accordingly annotated two specimens kept in the herbarium of the Escuela de Biología, Universidad de Costa Rica (USJ) with the proposed epythet “*Encyclia tardiflora*” (Morales 2001). Recording the presence of *P. prismatocarpa* in Costa Rican central Pacific lowlands, Pupulin (2001a) noted several characters useful to distinguish lowlands populations from typical forms of the species as occurring above 1000 m elevations, among which the abbreviate rhizome, the inflorescence produced on the previous pseudobulb, the non-fragrant flowers, the acute and basally reflexed sepals. It is obvious now that these populations, as well as the plant illustrated by Pupulin (2001a) should be assigned to *P. tardiflora*.

Other close relatives of *P. tardiflora* are *P. ionocentra*, and *P. neglecta*. However, the flowers of *P. ionocentra* lack purple spots, the sepals and petals are distinctly longer ( $> 4$  cm vs.  $< 2$  cm long in *P. tardiflora*) and the cordate-sagittate midlobe of the lip is caudate at apex (Mora-Retana & García-Castro 1990). On the other hand, *P. neglecta* presents a very long rhizome, narrowly ovate to linear-conic pseudobulbs, lax inflorescence and adaxially papillose sepals (Pupulin 2001b).

**ACKNOWLEDGEMENTS.** I thank Robert L. Dressler and the late Dora Emilia Mora-Retana for their useful observations on the complex discussed here. Wesley H. Higgins provided information about type collections. Sincere acknowledgements are extended to the staff of Jardín Botánico Lankester, Universidad de Costa Rica, for the support provided to my studies.
